

STL (Theory) – Inner Loop

Time series
decomposition

The main idea

Inner loop summary

ITERATE

1. **De-trend the data:** $y(t) - \text{trend}(t)$.
For the first iteration assume $\text{trend}(t) = 0$
2. **Extract seasonal(t)** using LOESS on the cycle-subseries of $y_{\text{detrend}}(t)$
3. **Extract trend(t)** by subtracting $\text{seasonal}(t)$ from $y(t)$ and smoothing using LOESS

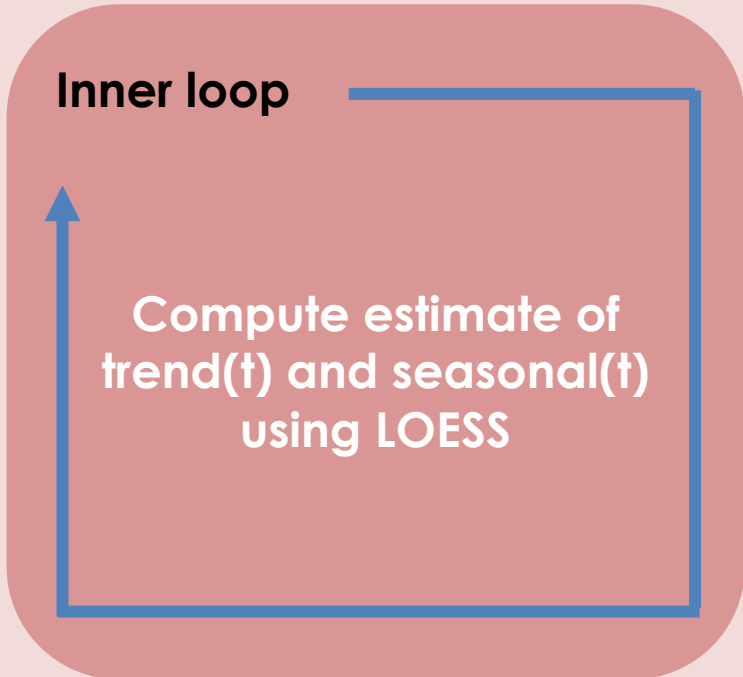

Inner loop summary

ITERATE

1. **De-trend the data:** $y(t) - \text{trend}(t)$.
For the first iteration assume $\text{trend}(t) = 0$
2. **Extract seasonal(t)** using LOESS on the cycle-subseries of $y_{\text{detrend}}(t)$
3. **Extract trend(t)** by subtracting seasonal(t) from $y(t)$ and smoothing using LOESS

Inner loop

Compute estimate of trend(t) and seasonal(t) using LOESS

A diagram illustrating the inner loop of the iterative process. It consists of a red rounded rectangle containing a blue square. The blue square has a blue arrow pointing upwards from its bottom edge to its top edge, indicating a loop. The text 'Inner loop' is positioned at the top left of the red rectangle, and the text 'Compute estimate of trend(t) and seasonal(t) using LOESS' is centered within the blue square.

Inner loop summary

ITERATE

1. **De-trend the data:** $y(t) - \text{trend}(t)$.
For the first iteration assume $\text{trend}(t) = 0$
2. **Extract seasonal(t)** using LOESS on the cycle-subseries of $y_{\text{detrend}}(t)$
3. **Extract trend(t)** by subtracting $\text{seasonal}(t)$ from $y(t)$ and smoothing using LOESS

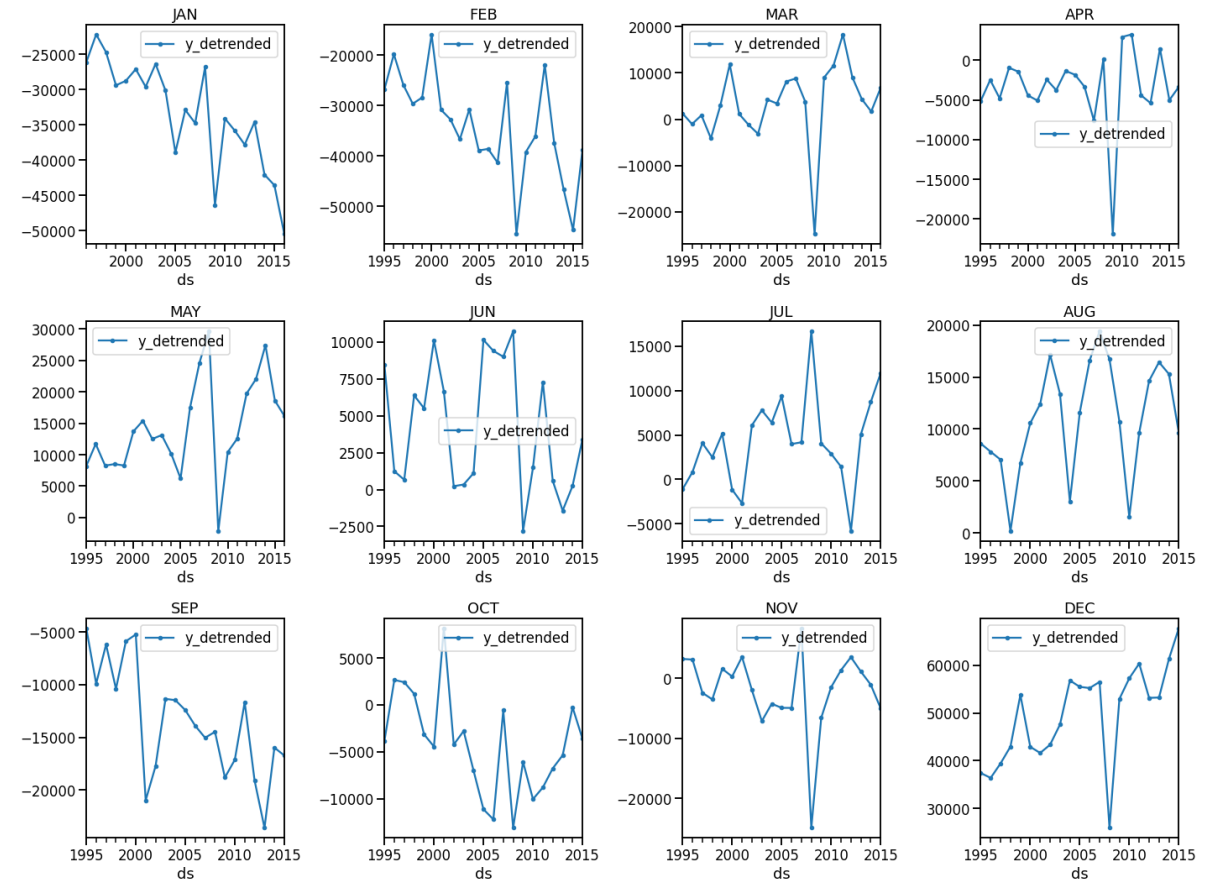

Inner loop

Compute estimate of $\text{trend}(t)$ and $\text{seasonal}(t)$ using LOESS

Extract seasonal component:

Step 1 – Apply LOESS to Cycle-Subseries

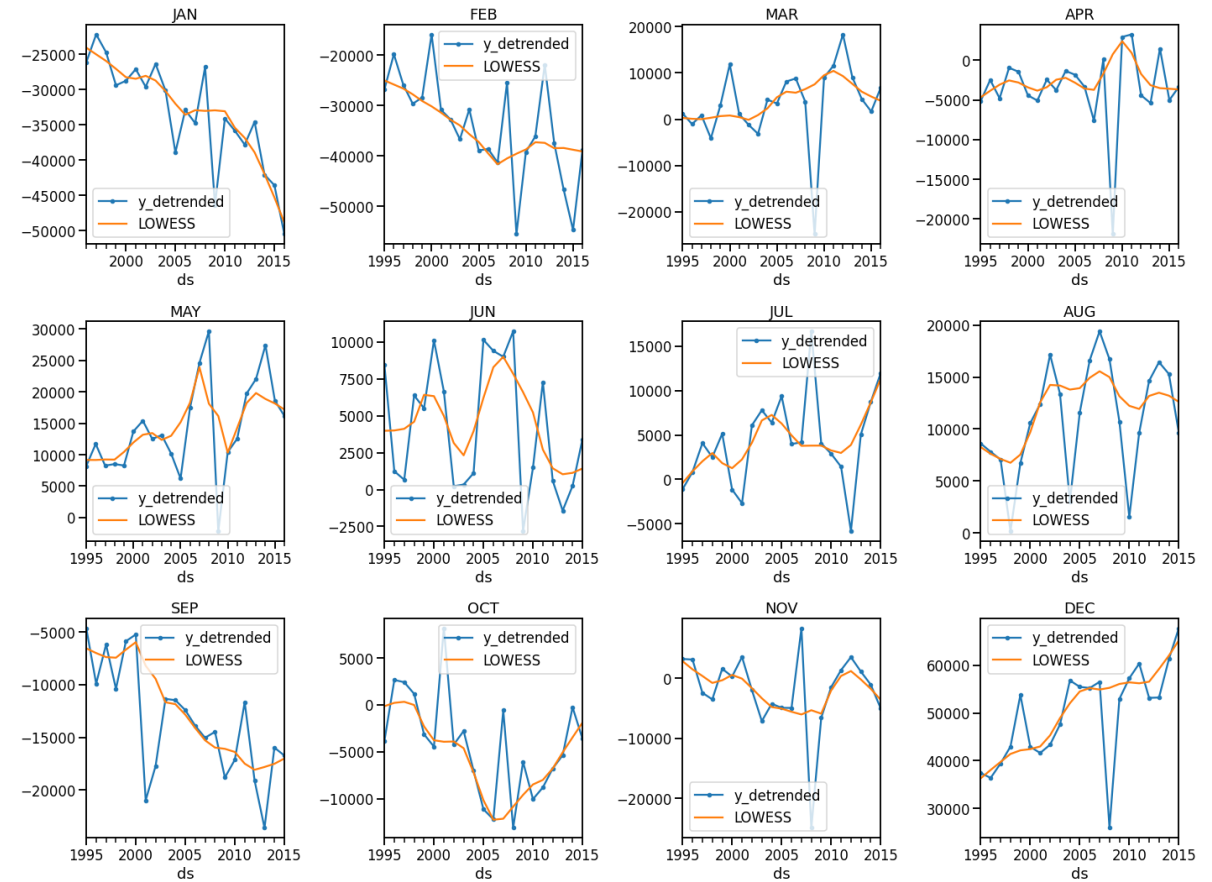

- User specifies n_p (aka period in statsmodels): number of periods in a seasonal cycle
- Compute all the cycle-subseries for $y_{\text{detrend}}(t)$
- Apply LOESS to each cycle-subseries with smoothing parameter n_s . n_s is set by the user.

Extract seasonal component:

Step 1 – Apply LOESS to Cycle-Subseries

- User specifies n_p (aka period in statsmodels): number of periods in a seasonal cycle
- Compute all the cycle-subseries for $y_{\text{detrend}}(t)$
- Apply LOESS to each cycle-subseries with smoothing parameter n_s . n_s is set by the user.
- Denote output as C_t

$$n_s = 7$$

Extract seasonal component:

Step 2 – De-trend the cycle-subseries

- Apply a series of moving averages to each smooth cycle-subseries:

$$[3 \times MA][n_p \times MA][n_p \times MA]$$

- Apply LOESS, with smoothing parameter n_l , to each smooth cycle-subseries:

$$L_t = [LOESS] [3 \times MA][n_p \times MA][n_p \times MA](C_t)$$

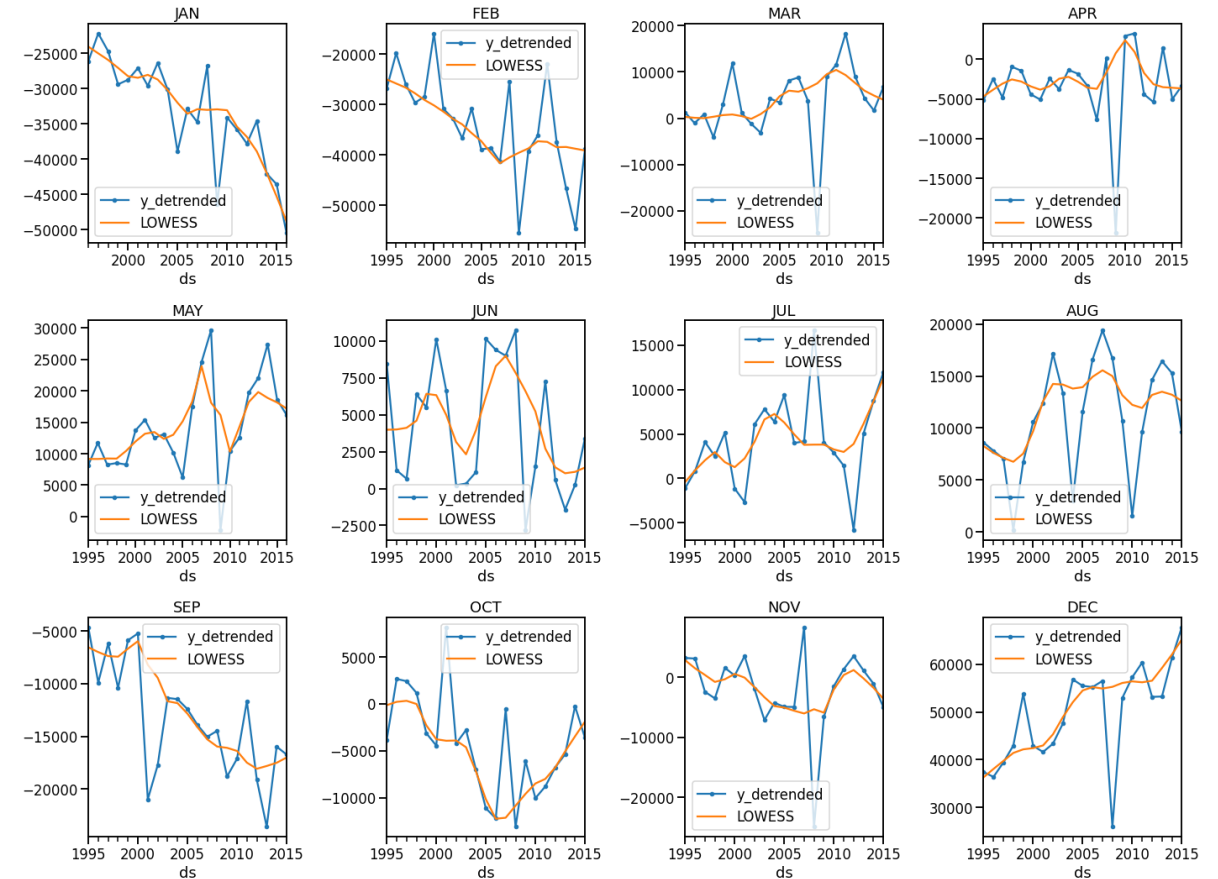

- Acts as a "low-pass filter" meaning that L_t represents any long term trend in the cycle-subseries
- De-trend the smoothed cycle-subseries. This gives the seasonality

$$S_t = C_t - L_t$$

Extract seasonal component:

Step 2 – De-trend the cycle-subseries

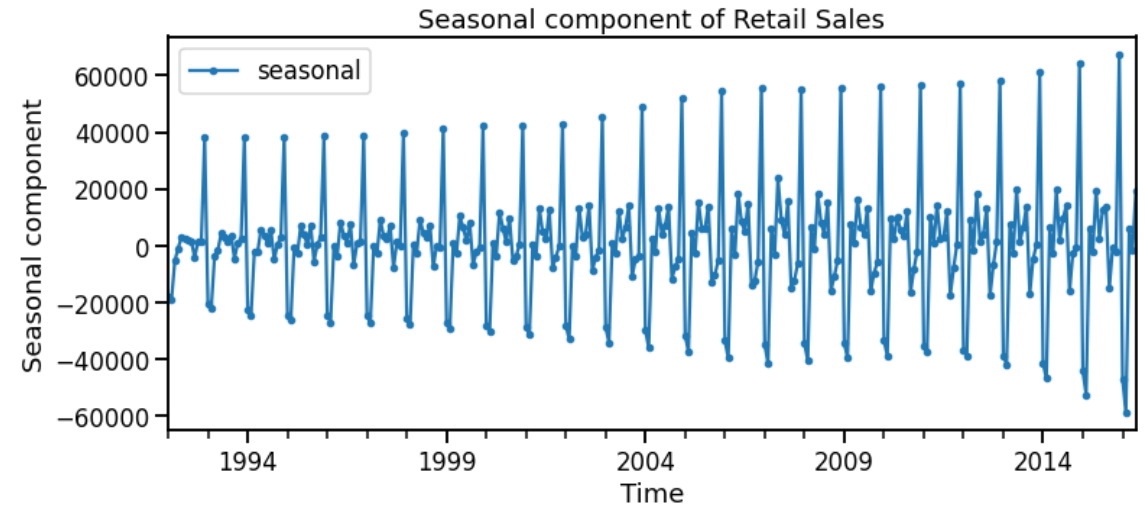

- As the seasonal component is derived from cycle-subseries it can vary in time!
- So seasonal component isn't exactly periodic over each cycle

Extract seasonal component:

Step 2 – De-trend the cycle-subseries

- As the seasonal component is derived from cycle-subseries it can vary in time!
- So seasonal component isn't exactly periodic over each cycle

Inner loop summary

ITERATE

1. **De-trend the data:** $y(t) - \text{trend}(t)$. For the first iteration assume $\text{trend}(t) = 0$
2. **Extract seasonal(t)** using LOESS on a set of time series derived from $y_{\text{detrend}}(t)$ called cycle-subseries. Will require us to specify the seasonal period.
3. **Extract trend(t)** by subtracting $\text{seasonal}(t)$ from $y(t)$ and smoothing using LOESS

Inner loop

Compute estimate of
 $\text{trend}(t)$ and $\text{seasonal}(t)$
using LOESS

Extract trend component

- De-seasonalize original series:

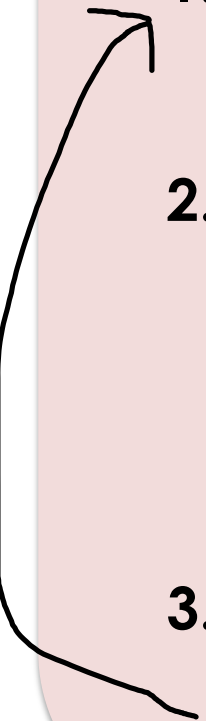

$$T_t^* = y_t - S_t$$

- Smooth T_t^* using LOESS, with smoothing parameter n_T , to give trend estimate:

$$T_t = LOESS(T_t^*)$$

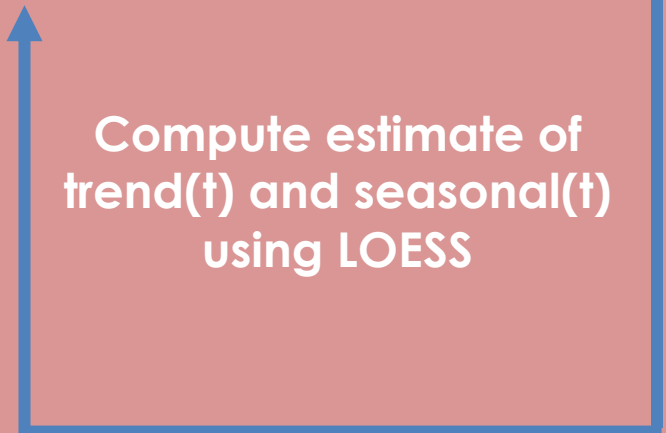

Inner loop summary

ITERATE

1. **De-trend the data:** $y(t) - \text{trend}(t)$. For the first iteration assume $\text{trend}(t) = 0$
 2. **Extract seasonal(t)** using LOESS on a set of time series derived from $y_{\text{detrend}}(t)$ called cycle-subseries. Will require us to specify the seasonal period.
 3. **Extract trend(t)** by subtracting $\text{seasonal}(t)$ from $y(t)$ and smoothing using LOESS
- 

Inner loop

Compute estimate of
 $\text{trend}(t)$ and $\text{seasonal}(t)$
using LOESS

Inner loop summary

ITERATE

1. **De-trend the data:** $y(t) - \text{trend}(t)$. For the first iteration assume $\text{trend}(t) = 0$
 2. **Extract seasonal(t)** using LOESS on a set of time series derived from $y_{\text{detrend}}(t)$ called cycle-subseries. Will require us to specify the seasonal period.
 3. **Extract trend(t)** by subtracting $\text{seasonal}(t)$ from $y(t)$ and smoothing using LOESS
- 

How many times to iterate, n_i ?

Until the outputted $\text{seasonal}(t)$ and $\text{trend}(t)$ are stable

Typically $n_i = 2$ or 3

Inner loop summary

ITERATE

- 
1. **De-trend the data:** $y(t) - \text{trend}(t)$. For the first iteration assume $\text{trend}(t) = 0$
 2. **Extract seasonal(t)** using LOESS on a set of time series derived from $y_{\text{detrend}}(t)$ called cycle-subseries. Will require us to specify the seasonal period.
 3. **Extract trend(t)** by subtracting $\text{seasonal}(t)$ from $y(t)$ and smoothing using LOESS

Robustness to outliers

Remember in LOESS that residuals are used to re-weight data during regression

Outer loop provides these weights for all uses of LOESS in inner loop

Parameters from inner loop

Symbol	Statsmodels	Description	Typical value
n_i	inner_iter	Number of inner loops	2 or 3
n_p	period	Number of periods in a seasonal cycle	Depends on data
n_s	seasonal	Window size for LOESS for cycle-subseries (aka seasonal component)	Depends on data
d_s	seasonal_deg	Degree for LOESS for cycle-subseries (aka seasonal component)	1 or in rare cases 0 (see notebook)
n_l	low_pass	Window size for LOESS for low pass filter of cycle-subseries	n_p or the next largest odd integer
d_l	low_pass_deg	Degree for LOESS for low pass filter of cycle-subseries	1
n_T	trend	Window size for LOESS for Trend	1.5 to $2 \times n_p$
d_T	trend_deg	Degree for LOESS for Trend	1

The main idea
